## 34 ${ }^{\text {th }}$ Indian National Mathematical Olympiad-2019

Date of Examination: 20 th January, 2019

## SOLUTIONS

1. Let ABC be a triangle with $\angle \mathrm{BAC}>90^{\circ}$. Let D be a point on the segment BC and E be a point on the line $A D$ such that $A D$ is tangent to the circumcircle of triangle $A C D$ at $A$ and $B E$ is perpendicular to AD . Given that $\mathrm{CA}=\mathrm{CD}$ and $\mathrm{AE}=\mathrm{CE}$, determine $\angle \mathrm{BCA}$ in degrees.

Sol. Construction : Extend
AE to meet the circumcircle of $\triangle \mathrm{ABC}$ at F
Claim : We prove that $E$ is the circumcentre of $\triangle A B C$
Let $\angle \mathrm{BAD}=\theta$ then $\angle \mathrm{ACD}=\theta($ By alternate segment theorem $)$
Join $\overline{\mathrm{BF}}$, we have
$\angle \mathrm{BCA}=\angle \mathrm{AFB}=\theta($ Angle made by $\overline{\mathrm{AB}})$
$\therefore$ We have $\mathrm{AB}=\mathrm{BF} \Rightarrow \triangle \mathrm{ABF}$ is isosceless
and $\mathrm{BE} \perp \mathrm{AF} \Rightarrow \mathrm{E}$ is mid point of AF

$\therefore \quad \mathrm{AE}=\mathrm{EF}$ and $\mathrm{AE}=\mathrm{CE}$ (given)
$\therefore \quad \mathrm{AE}=\mathrm{EF}=\mathrm{CE}$
$\Rightarrow E$ is the circum centre of $\triangle A B C$
$\therefore \angle \mathrm{ABF}=90^{\circ}[\mathrm{AF}$ is diameter]
$\therefore \quad 180-2 \theta=90^{\circ}$
$90^{\circ}=2 \theta$

$$
\begin{gathered}
\theta=45^{\circ} \\
\therefore \quad \angle \mathrm{BCA}=45^{\circ}
\end{gathered}
$$

2. Let $A_{1} B_{1} C_{1} D_{1} E_{1}$ be a regular pentagon. For $2 \leq n \leq 11$, let $A_{n} B_{n} C_{n} D_{n} E_{n}$ be the pentagon whose vertices are the midpoints of the sides of $A_{n-1} B_{n-1} C_{n-1} D_{n-1} E_{n-1}$. All the 5 vertices of each of the 11 pentagons are arbitrarily coloured red or blue. Prove that four points among these 55 points have the same colour and form the vertices of a cyclic quadrilateral.

Sol. Let $\mathrm{P}_{\mathrm{i}}$ be the polygon $\mathrm{A}_{\mathrm{i}} \mathrm{B}_{\mathrm{i}} \mathrm{C}_{\mathrm{i}} \mathrm{D}_{\mathrm{i}} \mathrm{E}_{\mathrm{i}}$ and O be the centre of the polygon
$\Rightarrow \mathrm{P}_{1}, \mathrm{P}_{3}, \mathrm{P}_{7}, \mathrm{P}_{9}, \mathrm{P}_{11}$ have the same orientation w.r.t. O
Let $\mathrm{C}_{\mathrm{i}}$ be the colour dominating in polygon P : [Which means which has atleast 3 of same colour]
Now in $\mathrm{P}_{1}, \mathrm{P}_{3}, \mathrm{P}_{7}, \mathrm{P}_{9}, \mathrm{P}_{11}$, atleast three will have colour with same $\mathrm{P}_{\mathrm{i}}$
Let them be $P_{1_{1}}, P_{1_{2}}, P_{1_{3}}$
Now the $\mathrm{C}_{\mathrm{i}}$ for these three be red (W. L. O. G.)
Now $P_{1_{1}}$ has 3 vertices of of same colour let them be $V_{1_{1}}, V_{1_{2}}, V_{1_{3}}$
Compare the vertices of $\mathrm{P}_{1_{1}}, \mathrm{P}_{1_{2}}$

If any of $V_{2_{4}}, V_{2_{5}}$ is not red then $\exists 2$ of $V_{2_{1}}, V_{2_{2}}, V_{2_{3}}$
which are red if they are $V_{1_{1}}, V_{1_{2}}$ then
$V_{1_{1}}, V_{1_{2}}, V_{2_{1}}, V_{2_{2}}$ is cyclic
so $V_{2_{4}}, V_{2_{5}}$ should be red
similarly $\mathrm{V}_{3_{4}}, \mathrm{~V}_{3_{5}}$ are red
Now we got $\mathrm{V}_{24}, \mathrm{~V}_{25}, \mathrm{~V}_{3_{4}}, \mathrm{~V}_{3_{5}}$ are cyclic and red
So we can find a cyclic quadrilateral.
Solution 2 : Consider a regular triangle in the plane ABC , whose vertices are coloured using only two colours Red and Blue.
then by PHP, two of the vertices must have same colour (say A \& B)
Now if we consider a regular pentagon then by using above result, we can assure that 3 vertices of pentagon is in Red and 2 vertices are blue and vice versa.

Now, we will analyse cases by case
Case-1 : When $4^{\text {th }}$ vertices will have some colour as 3 vertices, then we are done, as any 4 vertices of a regular pentagon will form a cyclic quadrilateral having all the 4 vertices same coloured.

Case-2 : Any of the 3 vertices Red and 2 are Blue coloured
Now, observe that in any pentagon two of the vertices will have same colour and it is also clear that, for this case we will have 6 pentagons (i.e. $1^{\text {st }}, 3^{\text {rd }}, 5^{\text {th }}, 7^{\text {th }}, 9^{\text {th }}$ and $11^{\text {th }}$ pentagon).

So, we have 6 such pantagon in which we will get 5 set of parallel lines (parallel to original pentagon)

Here $L_{1}, L_{2}, L_{3}, L_{4}, L_{5}$ are 5 set of parallel lines
So, once we consider there 5 set of parallel lines and we have six such lines (including $\mathrm{L}_{0}$ ) then by PHP, We will get 4 points having same colour and an isosceles trapezium which will be cyclic and hence we are done.

Case-3:2R and 3B: Same arguments as of case 2.
3. Let $\mathrm{m}, \mathrm{n}$ be distinct positive integers.

Prove that $\operatorname{gcd}(m, n)+\operatorname{gcd}(m+1, n+1)+\operatorname{gcd}(m+2, n+2) \leq 2|m-n|+1$.
Further, determine when equality holds.
Sol. let $\mathrm{m}>\mathrm{n}$
$\operatorname{gcd}(\mathrm{m}, \mathrm{n})=\operatorname{gcd}(\mathrm{m}, \mathrm{m}-\mathrm{n})=\mathrm{a}$
$\operatorname{gcd}(m+1, n+1)=\operatorname{gcd}(m+1, m-n)=b$
$\operatorname{gcd}(m+2, n+2)=\operatorname{gcd}(m+2, m-n)=c$
$\Rightarrow \operatorname{gcd}(\mathrm{a}, \mathrm{b})=1, \operatorname{gcd}(\mathrm{~b}, \mathrm{c})=1, \operatorname{gcd}(\mathrm{a}, \mathrm{c}) / 2$

## Case-1 :

If $\operatorname{gcd}(a, c)=1, d=m-n$
a/d, b/d, c/d
$\Rightarrow \mathrm{abc} / \mathrm{d}$
$\Rightarrow \mathrm{d} \geq \mathrm{abc}$
$\Rightarrow 2 \mathrm{~d}+1 \geq 2 \mathrm{abc}+1$
if atleast one of $a, b, c>1$ let it be $b$
$\Rightarrow 2 \mathrm{abc}+1=\mathrm{abc}+\mathrm{abc}+1$
$\geq 2 \mathrm{ac}+\mathrm{dbc}+1$
$\geq \mathrm{ac}+\mathrm{ac}+\mathrm{b}+1$
$\geq a+c+b+1$
$>\mathrm{a}+\mathrm{b}+\mathrm{c}$
so we are done
if all of $a, b, c=1$
then

$$
2 \mathrm{abc}+1=3=\mathrm{a}+\mathrm{b}+\mathrm{c}
$$

so we are done
Case-2 : $\operatorname{gcd}(\mathrm{a}, \mathrm{c})=2$

$$
\text { Now } \mathrm{a}=2 \mathrm{a}^{\prime}, \mathrm{c}=2 \mathrm{c}^{\prime} \Rightarrow \operatorname{gcd}\left(\mathrm{a}^{\prime} \mathrm{c}^{\prime}\right)=1
$$

$\Rightarrow 2 a^{\prime} \mathrm{bc} / \mathrm{d} \Rightarrow \mathrm{d} \geq 2 \mathrm{a}^{\prime} \mathrm{bc} c^{\prime}$

so equality holds when $\mathrm{a}=\mathrm{b}=\mathrm{c}=1 \Rightarrow \mathrm{a}^{\prime}=\mathrm{c}^{\prime}=1, \mathrm{~b}=1$

$$
\mathrm{d}=\mathrm{abc}
$$

which means at
$|\mathrm{m}-\mathrm{n}|=1$; for $\mathrm{m}, \mathrm{n}$ consecutive positive integers
$|\mathrm{m}-\mathrm{n}|=2$ and $\mathrm{m}, \mathrm{n}$ are even positive integers
4. Let $n$ and $M$ be positive integers such that $M>n^{n-1}$. Prove that there are $n$ distinct primes $\mathrm{p}_{1}, \mathrm{p}_{2}, \mathrm{p}_{3} \ldots, \mathrm{p}_{\mathrm{n}}$ such that $\mathrm{p}_{\mathrm{j}}$ divides $\mathrm{M}+\mathrm{j}$ for $1 \leq \mathrm{j} \leq \mathrm{n}$.
Sol. $\mathrm{n}, \mathrm{m} \in \mathrm{I}^{+}$,
$\mathrm{M}>\mathrm{n}^{\mathrm{n}-1}, \mathrm{n} \rightarrow$ distinct primes
$P_{1}, P_{2}, \ldots \ldots P_{n}$ such that $p_{j}$ divides $M+j$ for $i \leq j \leq n$
Case-1 : If $M+j$ has atleast ' $n$ ' prime divisiors then $p_{j}$ divides $m+j$ for $\mathrm{i} \leq \mathrm{j}$ for at least ' n ' distinct primes.
Case-2 : When $m+j$ has $n-1$ or less prime divisors,
Let $\mathrm{M}+\mathrm{j}=\mathrm{P}_{1}^{\mathrm{m}_{1}} . \mathrm{P}_{2}^{\mathrm{m}_{2}} \ldots \ldots . \mathrm{P}_{\mathrm{t}}^{\mathrm{m}_{\mathrm{t}}}$ where $\mathrm{P}_{1}, \mathrm{P}_{2} \ldots . . \mathrm{P}_{\mathrm{t}}$ are main distinct $\mathrm{t} \leq \mathrm{n}-1$

## Claim :

Let us assume that for $\mathrm{P}_{\mathrm{i}}, \mathrm{P}^{\mathrm{n}_{\mathrm{i}}}$ is maximum,
Suppose ' $P^{\prime}$ is chosen for $\mathrm{M}+\mathrm{i} \& \mathrm{M}+\mathrm{j} \& \mathrm{P}^{\mathrm{m}} \& \mathrm{P}^{\mathrm{n}}$ divides $\mathrm{M}+\mathrm{i} \& \mathrm{M}+\mathrm{j}$
when $n \geq m$
$\Rightarrow \mathrm{P}^{\mathrm{m}}$ divides $(\mathrm{m}+\mathrm{j})-(\mathrm{m}+\mathrm{i})=\mathrm{j}-\mathrm{i} \leq \mathrm{n}-1$
but $\mathrm{P}^{\mathrm{m}} \geq(\mathrm{m}+\mathrm{j})^{\frac{1}{\mathrm{n}-1}} \geq\left(\mathrm{n}^{\mathrm{n}-1}\right)^{\frac{1}{\mathrm{n}-1}}=\mathrm{n}$
Which leads to a contradiction.
5. Let $A B$ be a diameter of a circle $\Gamma$ and let $C$ be a point on $\Gamma$ different from $A$ and $B$. Let $D$ be the foot of perpendicular from $C$ on to $A B$. Let $K$ be a point of the segment $C D$ such that $A C$ is equal to the semiperimeter of the triangle ADK. Show that the excircle of triangle ADK opposite $A$ is tangent to $\Gamma$.
Sol. Since if two circles touch each other then difference between their centre is the difference between their radii if two circle touch internally
Our aim is to show $\mathrm{OI}_{\mathrm{A}}=\mathrm{R}-\mathrm{r}$
Let $\mathrm{AD}=\mathrm{a}, \mathrm{AK}=\mathrm{c}, \mathrm{KD}=\mathrm{b}$
let $A C=x, X I_{A}=r, x=\frac{a+b+c}{2}$
Since exradius $\triangle A D K$ is $r=\frac{K D+A K-A D}{2}$

Also $\quad O X=|A D+D X-A O|=|a+r-R|$
$\mathrm{OX}=|\mathrm{x}-\mathrm{R}|$
In $\Delta \mathrm{OI}_{\mathrm{A}} \mathrm{X} \quad \Rightarrow \mathrm{OI}_{\mathrm{A}}^{2}=\mathrm{OX}^{2}+\mathrm{XI}_{\mathrm{A}}^{2}$
$=(\mathrm{x}-\mathrm{R})^{2}+\mathrm{r}^{2}$
$=\mathrm{x}^{2}+\mathrm{R}^{2}-2 \mathrm{xR}+\mathrm{r}^{2}$
$=R^{2}+r^{2}+2 a R-2 x R$, from (A)
$R^{2}+r^{2}-2 R(x-a)=R^{2}+r^{2}-2 r R$
$\mathrm{OI}_{\mathrm{A}}{ }^{2}=(\mathrm{R}-\mathrm{r})^{2}$
$\therefore \mathrm{OI}_{\mathrm{A}}=\mathrm{R}-\mathrm{r}$
6. Let $f$ be a function defined from the set $\{(x, y): x, y$ real, $x y \neq 0\}$ to the set of all positive real numbers such that
(i) $f(\mathrm{xy}, \mathrm{z})=f(\mathrm{x}, \mathrm{z}) f(\mathrm{y}, \mathrm{z})$, for all $\mathrm{x}, \mathrm{y} \neq 0$;
(ii) $f(\mathrm{x}, 1-\mathrm{x})=1$, for all $\mathrm{x} \neq 0,1$.

Prove that
(a) $f(\mathrm{x}, \mathrm{x})=f(\mathrm{x},-\mathrm{x})=1$, for all $\mathrm{x} \neq 0$;
(b) $f(\mathrm{x}, \mathrm{y}) f(\mathrm{y}, \mathrm{x})=1$, for all $\mathrm{x}, \mathrm{y} \neq 0$.

Sol. Given information is insufficient to prove the required results. One such counter example is as follows. Counter example :
$f(x, y)=\left\{\begin{array}{cl}g(x) & , y=c \\ 1, & y \neq c\end{array}\right.$
g is some multiplicative function such that $\mathrm{g}(1-\mathrm{c})=1$
Now, $g(x y)=g(x) \cdot g(y)$
$\Rightarrow f(\mathrm{xy}, \mathrm{z})=f(\mathrm{x}, \mathrm{z}) \cdot f(\mathrm{y}, \mathrm{z})$

$$
f(x, 1-x)=\left\{\begin{array}{cll}
g(x) & , & x=1-c \\
1 & , & x \neq 1-c
\end{array}=1\right.
$$

One such $g(x)=x^{2}$, and take $c=2$, where $c$ is some real number. Here
for $1-\mathrm{x} \neq \mathrm{c}, \mathrm{f}(\mathrm{x}, 1-\mathrm{x})=1$
and for $1-x=c$ or $x=1-c, f(x, 1-x)=f(1-c, c)=g(1-c)=1$
Hence $f(x, 1-x)=1$
Now observe:
$\mathrm{f}(2,2)=\mathrm{g}(2)=2^{2} \neq 1$
Also for $\mathrm{x}=\mathrm{y}=2$
$f(x, y) f(y, x)=(f(2,2))^{2}=(g(2))^{2}=16 \neq 1$
Hence the given question is incorrect.
